

Security Operations Center - Threat Analysis Report

Threat Level: LOW | **Total Alerts:** 6 **Generated:** 2025-11-05T22:21:42.280Z

Executive Summary

Six low-severity alerts were detected on the Wazuh server, all related to PAM (Pluggable Authentication Modules) login session events and SSH authentication success. All alerts are associated with internal system activity and lack indicators of external threats, lateral movement, or malicious behavior. No infrastructure, internal, or external threat classifications were triggered. The events appear to represent normal authentication workflows, likely from legitimate administrative access or automated system processes. No immediate risk is identified, and no external connections or suspicious activities were observed. All alerts are consistent with routine system operations and do not require urgent action.

Key Findings

- All six alerts are low-severity and pertain to SSH login sessions and authentication events.
- No external IPs, suspicious domains, or anomalous network behavior were detected.
- All events originate from the Wazuh server itself, indicating internal system activity.
- No evidence of brute-force attempts, credential misuse, or unauthorized access.
- Alerts are consistent with standard authentication lifecycle events (session open, success, close).

MITRE ATT&CK Mapping

- **T1078** - Valid Accounts (Defense Evasion)
- **T1021.004** - SSH (Lateral Movement)

Immediate Actions Required

1. Monitor Wazuh server for repeated SSH login events over the next 24 hours.
2. Ensure SSH access is restricted to authorized users and enforced with key-based authentication.
3. Confirm no unauthorized scripts or automated tools are initiating login sessions.
4. Review system logs for any associated failed attempts or anomalies.
5. Maintain current monitoring posture; no further escalation required at this time.
